Abstract. We study a simplified mean-field potential consisting of a finite radial square well plus a radial δ - δ' contact potential in order to describe single neutron energy levels. This is a limiting case of the Woods-Saxon potential, where the Dirac- δ takes account of the nuclear spin-orbit interaction. This contact potential is defined by appropriate matching conditions for the wave functions at the well edge, thereby fixing a self adjoint extension of the non-singular Hamiltonian. Since this model admits exact solutions for the wave function, we are able to characterize and calculate the number of bound states. We also extend some well-known properties of certain spherically symmetric potentials. The results obtained are tested with experimental and numerical data in the double magic nuclei ^{132}Sn and ^{208}Pb with an extra neutron. The presence of resonances, defined as unstable quantum states, is also considered.

Keywords: Woods-Saxon nuclear model, contact potentials, self adjoint extension, bound states, resonances

1. Introduction

In one-dimensional non-relativistic quantum mechanics, point potentials or potentials supported on one or a discrete collection of points, like the Dirac delta interactions, have deserved considerable attention recently (see [1] and references quoted therein). These potentials are often exactly solvable and therefore, provide a good insight for some quantum phenomena like scattering. In addition, they serve as a fair approximation for various types of interactions, as very short range interactions between a single particle and a fixed heavy source as well as a contact interaction in the centre of mass of two particles. This is the origin of the name *contact potentials*. They also function as suitable approximations when the particle wavelength is much larger than the range of the potential. In spite of their simplicity, they have a vast amount of applications in modelling real physical systems, as we can see for instance in a recent review [1], some books [2, 3] and the references therein. The landmark example in solid state physics is a limiting case of the Kronig-Penney model in which a countably infinite set of Dirac delta interactions are periodically distributed along a straight line [4, 5].

Other examples of physical interest are the following: a Bose-Einstein condensation in a harmonic trap with a tight and deep “dimple” potential, modelled by a Dirac delta function [6]; a non-perturbative study of the entanglement of two directed polymers subject to repulsive interactions given by a Dirac delta potential [7]; light propagation in a one-dimensional realistic dielectric superlattice, modelled by means of a periodic array of these functions for the cases of transverse electric, transverse magnetic, and omnidirectional polarization modes [8].

In the context of the present article, the Dirac delta interaction has been used for the calculation of resonant parameters and energy spectrum in [9]. Recently, it has also been employed to study the spectral function of the unbound nucleus ^{25}O [10]. In the latter case, a comparison of the spectrum obtained between the δ potential

versus the nuclear non-singular mean-field is performed. In order to test our model, we will also compare with the regular mean-field potential for ^{133}Sn and ^{209}Pb .

From a purely mathematical point of view, one-dimensional contact potentials have been studied as self adjoint extensions of the kinetic energy operator $-d^2/dx^2$ [3, 11]. This approach has been used to construct several one-dimensional models which go beyond the Dirac delta potential [12]. A discussion on the physical meaning of the one-dimensional contact potentials constructed as self adjoint extensions of the kinetic energy operator is given in [13]. It is remarkable that, inspired in the physics of contact interactions, new mathematics has been developed [14].

Along the present manuscript, and for reasons that we shall expose below, we are going to consider a linear combination of a Dirac delta and a δ' interaction, both supported on a hollow sphere of radius x_0 . Thus, this interaction is represented by a potential of the form

$$V(x) = v_1 \delta(x - x_0) + v_2 \delta'(x - x_0). \quad (1.1)$$

As is well known, spherically symmetric three-dimensional Schrödinger equations yield, essentially, to a one-dimensional problem. When working with the radial equation, the δ - δ' interaction supported on the sphere become a one-dimensional δ - δ' interaction supported on the point $x_0 > 0$. A self adjoint determination for the Hamiltonian $H = -d^2/dx^2 + V(x)$ with the potential (1.1) in one dimension has been discussed in [15]. Although the definition for the δ interaction is universally accepted, this is not the case for the δ' term, for which at least two definitions are consistent with its desirable properties [16, 17]. In this paper, following the lines developed in [15, 18], we shall use the so called *local* δ' interaction since it is compatible with the δ potential in such a way that the total Hamiltonian $H = -d^2/dx^2 + V(x)$ is self adjoint. As we shall see, since both interactions are supported on the same point, the proposed model naturally leads to this determination which is beautifully given by a proper choice of matching conditions for the wave functions at x_0 .

Accordingly, the same choice of the Hamiltonian $H = -d^2/dx^2 + V(x)$ has been used in a study in which the interaction (1.1) plays a fundamental role: the approximation of a system formed by two thin plates in order to describe the quantum vacuum fluctuations in the presence of boundaries: the Casimir effect [19]. Some other discussions on properties of contact potentials are given in [16, 20–22] and their use in supersymmetric quantum mechanics is shown in [23, 24] and references quoted therein. We do not intend to be exhaustive and just mention recent literature.

Given all the above, and since the δ - δ' interaction arises naturally as a limiting case of the Woods-Saxon potential, we intend to employ it to describe neutron energy levels in double magic nuclei. The main advantage of this approach is that the wave function can be easily solved in terms of well-known special functions. This enables us to derive analytic properties of the neutron energy levels structure.

This article is organized as follows. We pose and justify the problem under our consideration in section 2: a singular single particle mean-field potential with radial δ and δ' terms. In section 3, we derive the secular equation for which the solutions give the bound states. In section 4, we study the existence and localization of bound states, giving some rigorous results. These findings are tested with the nuclei ^{133}Sn and ^{209}Pb in section 5, the latter being of some relevance in particle astrophysics [25]. The analysis of resonances is necessary because most of the known quantum states in nuclear or atomic physics are unstable; therefore, we study the resonances arisen in our example in section 6. Concluding remarks, and two appendices, one devoted to some comments on the self adjointness of the Hamiltonian and the other to the proofs of the main results of the text, give an end to this paper.

2. Singular single particle mean-field potential

The singular radial δ - δ' interaction may be obtained as a limiting case of a regular mean-field potential which includes volume, surface, and spin-orbit parts, as the one used to study atomic nuclei [26–28]. In order to make the link between the strength which appears in the radial δ - δ' interaction, with real physical parameters, we start with the following three-dimensional single particle Hamiltonian in the centre of mass system,

$$H(\mathbf{r}) = -\frac{\hbar^2}{2\mu} \nabla_{\mathbf{r}}^2 + U_0(r) + U_{so}(r)(\mathbf{L} \cdot \mathbf{S}) + U_q(r). \quad (2.1)$$

The reduced mass of the system is denoted by μ , being $U_0(r)$, $U_{so}(r)$, and $U_q(r)$, essentially, the Woods-Saxon potential (WS) [29], its first and second derivative, respectively,

$$U_0(r) = -V_0 f(r) = -V_0 \frac{1}{1 + e^{(r-R)/a}}, \quad (2.2)$$

$$U_{so}(r) = \frac{V_{so}}{\hbar^2} f'(r) = -\frac{V_{so}}{a\hbar^2} \frac{e^{(r-R)/a}}{(1 + e^{(r-R)/a})^2}, \quad (2.3)$$

$$U_q(r) = V_q f''(r) = -\frac{V_q}{a^2} \frac{e^{(r-R)/a} (1 - e^{(r-R)/a})}{(1 + e^{(r-R)/a})^3}. \quad (2.4)$$

Since we only study configurations with an extra neutron, the Coulombic potential is not included in the Hamiltonian. The strengths V_0 and V_{so} of the WS and the spin-orbit, respectively, are positive defined in order to reproduce the experimental magic number [30], while the sign of V_q can be selected in order to fit with the experimental data. This second derivative of the WS may be used as a form factor in the transition operator for the quadrupolar electric transition E2 in the Interacting Boson Approximation model [31]. The nuclear radius R is parametrized in terms of the nuclear mass $A = N + Z$ as $R = r_0 A^{1/3}$, being r_0 constant and N , Z the number of neutrons and protons, respectively. The parameter a gives the thickness of the surface of $f(r)$. The nuclear shell model considers N or Z as a magic number, and optimized all these parameters in a way to reproduce, as well as possible, the low-lying energy levels of the nuclei with one extra neutron or proton [32]. Typical values for the parameters are $r_0 = 1.27$ fm, $a = 0.67$ fm, $V_0 = 51 \pm 33(N - Z)/A$ MeV, with $+$ ($-$) for proton (neutron) [33].

Going back to the Hamiltonian (2.1), we rewrite the kinetic operator in terms of the orbital angular momentum \mathbf{L} and the radial coordinates as

$$-\frac{\hbar^2}{2\mu} \nabla_r^2 = -\frac{\hbar^2}{2\mu} \left[\frac{1}{r^2} \frac{\partial}{\partial r} \left(r^2 \frac{\partial}{\partial r} \right) - \frac{\mathbf{L}^2/\hbar^2}{r^2} \right]. \quad (2.5)$$

The eigenfunctions of the corresponding three-dimensional stationary Schrödinger equation are factored into a radial $u_{n\ell j}(r)/r$ and angular part $\mathcal{Y}_{\ell j m}(\theta, \phi)$. The latter fulfils

$$\mathbf{L}^2 \mathcal{Y}_{\ell j m}(\theta, \phi) = \hbar^2 \ell(\ell + 1) \mathcal{Y}_{\ell j m}(\theta, \phi), \quad (\mathbf{L} \cdot \mathbf{S}) \mathcal{Y}_{\ell j m}(\theta, \phi) = \hbar^2 \xi_{\ell j} \mathcal{Y}_{\ell j m}(\theta, \phi), \quad (2.6)$$

so that each of the $\mathcal{Y}_{\ell j m}(\theta, \phi)$ is a simultaneous eigenfunction of the operators \mathbf{L}^2 , \mathbf{S}^2 , $\mathbf{J}^2 = (\mathbf{L} + \mathbf{S})^2$ and J_z [33]. We have also defined

$$\xi_{\ell j} = \frac{1}{2} \left(j(j+1) - \ell(\ell+1) - \frac{3}{4} \right) = \begin{cases} \frac{\ell}{2} & \text{for } j = \ell + \frac{1}{2}, \\ -\frac{(\ell+1)}{2} & \text{for } j = \ell - \frac{1}{2}, \end{cases} \quad (2.7)$$

where ℓ takes values in the non-negative integers \mathbb{N}_0 . For $\ell = 0$ the only possibility is $j = 1/2$ so $\xi_{0j} = 0$. Using the above relations, the radial part fulfils $H(r) u_{n\ell j}(r) = E_{n\ell j} u_{n\ell j}(r)$ where

$$H(r) = -\frac{\hbar^2}{2\mu} \left[\frac{d^2}{dr^2} - \frac{\ell(\ell+1)}{r^2} \right] - V_0 f(r) + V_{so} \xi_{\ell j} f'(r) + V_q f''(r). \quad (2.8)$$

Notice, that the spin-orbit interaction is defined without the $1/r$ factor as usual [34, 35]. This may be done since the nuclear spin-orbit does not have the same origin as the one in the atom, and yet it is not well understood. In table 1, we show that the change in the spectrum of energy when the $1/r$ term is omitted is small, a fact supporting our pragmatic use of the spin-orbit form factor.

Finally, in order to reach the explicit form of the effective potential used thorough the present article, we take the limit $a \rightarrow 0^+$. Note that

$$\lim_{a \rightarrow 0^+} U_0(r) = \lim_{a \rightarrow 0^+} (-V_0) f(r) = \begin{cases} -V_0 & \text{if } r < R \\ -V_0/2 & \text{if } r = R \\ 0 & \text{if } r > R \end{cases} = V_0 [\theta(r - R) - 1], \quad r \geq 0, \quad (2.9)$$

Table 1. Neutron energy levels (MeV) in the core of ^{208}Pb using $1/r V_{so} \xi_{\ell j} f'(r)$ (second column) versus $V_{so} \xi_{\ell j} f'(r)$ (third column) as the radial form factor of the spin-orbit interaction.

State ($n\ell_j$)	$E_{n\ell_j}^*$	$E_{n\ell_j}$
$0s_{1/2}$	-40.230	-40.230
$0p_{3/2}$	-36.326	-36.391
$0p_{1/2}$	-35.926	-35.817
$1s_{1/2}$	-29.619	-29.619
$1p_{3/2}$	-23.467	-23.644
$1p_{1/2}$	-22.691	-22.364
$2s_{1/2}$	-15.294	-15.294
$2p_{3/2}$	-8.349	-8.612
$2p_{1/2}$	-7.404	-6.875

where $\theta(x)$ is the Heaviside step function. The function $f(r)$ can be seen as a distribution on a certain space of test functions, such as the Schwartz space. Then, if $\psi(r)$ is an arbitrary test function we denote the action of the distribution $f(r)$ on $\psi(r)$ by $\langle \psi(r) | f(r) \rangle = \int_0^\infty \psi^*(r) f(r) dr$. For the first derivative we obtain

$$\lim_{a \rightarrow 0^+} \langle \psi(r) | \frac{d}{dr} f(r) \rangle = - \lim_{a \rightarrow 0^+} \langle \psi'(r) | f(r) \rangle = - \langle \psi'(r) | 1 - \theta(r - R) \rangle = \langle \psi(r) | -\delta(r - R) \rangle. \quad (2.10)$$

This holds since the Dirac delta is the derivative of the Heaviside step function, from the point of view of distributions. Consequently,

$$\lim_{a \rightarrow 0^+} V_{so} \xi_{\ell j} f'(r) = -V_{so} \xi_{\ell j} \delta(r - R). \quad (2.11)$$

In the same way, we obtain the following expression for the second derivative:

$$\lim_{a \rightarrow 0^+} U_q(r) = \lim_{a \rightarrow 0^+} V_q f''(r) = -V_q \delta'(r - R). \quad (2.12)$$

In view of these considerations, the Hamiltonian (2.8) turns into

$$H_{\text{sing}}(r) = -\frac{\hbar^2}{2\mu} \left[\frac{d^2}{dr^2} - \frac{\ell(\ell+1)}{r^2} \right] + V_0 [\theta(r - R) - 1] - V_{so} \xi_{\ell j} \delta(r - R) - V_q \delta'(r - R). \quad (2.13)$$

where the singular (contact) terms are already included. A comment on the δ' contribution in (2.13) is in order here. As explained in [Appendix A](#), the δ - δ' perturbation is defined using the formalism of self adjoint extensions of symmetric (formally Hermitian) operators with equal deficiency indices. This gives two options for the δ' term. The former is a δ' which is a weak limit of a sequence of odd functions, as customary in the theory of distributions [36]. This δ' is often called the *non-local* δ' [16]. However, this choice is incompatible with the Dirac- δ [17], so that we have to use the other choice, the *local* δ' interaction, which is defined by matching conditions established at the point supporting the interaction.

Thus, bearing in mind that $R \gg a$, we can consider the above simplified one-dimensional Hamiltonian (2.13) as a mean-field potential to describe neutron energy levels. One of the main advantages of the derived model is that the eigenvalue equation $H_{\text{sing}}(r) u_\ell(r) = E_{n\ell_j} u_\ell(r)$ can be solved exactly for the wave function⁵ in terms of Bessel functions. Consequently, the main findings of the text are based on the properties of these functions.

3. Solutions of the singular Schrödinger equation

In this section, we determine the eigenfunctions of the singular Hamiltonian (2.13),

$$\left[-\frac{d^2}{dr^2} + \frac{\ell(\ell+1)}{r^2} - \frac{2\mu E}{\hbar^2} + \frac{2\mu V_0}{\hbar^2} (\theta(r - R) - 1) + \alpha \delta(r - R) + \beta \delta'(r - R) \right] u(r) = 0, \quad (3.1)$$

where

$$\alpha = -\frac{2\mu}{\hbar^2} V_{so} \xi_{\ell j}, \quad \beta = -\frac{2\mu}{\hbar^2} V_q. \quad (3.2)$$

⁵ For simplicity, and when no confusion arises, we will use abbreviated notation such as $u_\ell \equiv u_{n\ell_j}$.

The radial Schrödinger equation is defined on the interval $0 \leq r < \infty$. Due to the presence of the contact potential, we divide this semi-axis into two regions: inside ($0 \leq r < R$) and outside the nucleus ($R < r$). We shall obtain the wave function on each region and then apply suitable matching conditions at $r = R$, thus defining the singular part of the Hamiltonian.

3.1. Wave equation inside the nucleus

In the study of the solutions inside the nucleus, we consider energy values $E > -V_0$. Hence, if we perform the transformations

$$x = \gamma r \quad y_\ell(x) = u_\ell(r), \quad \gamma = \frac{\sqrt{2\mu(V_0 + E)}}{\hbar}, \quad x \in [0, \gamma R), \quad (3.3)$$

then, equation (3.1) becomes a Riccati-Bessel differential equation:

$$\frac{d^2 y_\ell(x)}{dx^2} - \frac{\ell(\ell+1)}{x^2} y_\ell(x) + y_\ell(x) = 0, \quad \ell \in \mathbb{N}_0. \quad (3.4)$$

For each particular value of the orbital angular momentum ℓ , the general solution is given by

$$y_\ell(x) = \sqrt{x} \left(A_\ell J_{\ell+\frac{1}{2}}(x) + B_\ell Y_{\ell+\frac{1}{2}}(x) \right), \quad (3.5)$$

where $J_{\ell+1/2}(x)$ and $Y_{\ell+1/2}(x)$ denote the Bessel functions of first and second kind, respectively, being A_ℓ and B_ℓ arbitrary constants. For small values of the positive variable x , the asymptotic forms of the aforementioned Bessel functions are given by

$$J_{\ell+\frac{1}{2}}(x) \sim \frac{1}{\Gamma(\ell+\frac{3}{2})} \left(\frac{x}{2}\right)^{\ell+\frac{1}{2}}, \quad Y_{\ell+\frac{1}{2}}(x) \sim -\frac{\Gamma(\ell+\frac{1}{2})}{\pi} \left(\frac{2}{x}\right)^{\ell+\frac{1}{2}}. \quad (3.6)$$

Hence, if we are looking for square integrable solutions, we should impose $B_\ell = 0$ for $\ell \neq 0$, since $\sqrt{x} Y_{\ell+1/2}(x)$ behaves near zero as $x^{-\ell}$. For $\ell = 0$, the radial Hamiltonian is not self adjoint, although it admits a one parameter family of self adjoint extensions [37]. To fix one of these, we need to set boundary conditions at the origin for the functions $y_0(x)$ in the domain of the radial Hamiltonian. The simplest possibility is $y_0(0) = 0$, which forces the choice $B_0 = 0$. In consequence, $B_\ell = 0 \forall \ell \in \mathbb{N}_0$. On the other hand, it is obvious after (3.6) that $\sqrt{x} J_{\ell+\frac{1}{2}}(x)$ is zero at the origin and therefore square integrable on the finite interval considered. Consequently, the admissible solutions are just

$$u_\ell(r) = A_\ell \sqrt{\gamma r} J_{\ell+\frac{1}{2}}(\gamma r), \quad r \in [0, R), \quad \ell \in \mathbb{N}_0. \quad (3.7)$$

3.2. Wave equation outside the nucleus

For values of r with $R < r$, we have to solve the Schrödinger equation (3.1) with $V_0 = 0$. As we are looking for bound states, we require $E < 0$. Then, we first proceed with the following changes:

$$z = \kappa r, \quad y_\ell(z) = u_\ell(r), \quad \kappa = \frac{\sqrt{2\mu|E|}}{\hbar}, \quad z \in (\kappa R, \infty), \quad (3.8)$$

which transform (3.1) into the following differential equation:

$$\frac{d^2 y_\ell(z)}{dz^2} - \frac{\ell(\ell+1)}{z^2} y_\ell(z) - y_\ell(z) = 0, \quad \ell \in \mathbb{N}_0. \quad (3.9)$$

For any value of ℓ , the general solution of (3.9) is given by

$$y_\ell(z) = \sqrt{z} \left(C_\ell I_{\ell+\frac{1}{2}}(z) + D_\ell K_{\ell+\frac{1}{2}}(z) \right). \quad (3.10)$$

Here, $I_{\ell+1/2}(z)$ and $K_{\ell+1/2}(z)$ are the modified Bessel functions of first and second kind, respectively, being C_ℓ and D_ℓ arbitrary constants. Again, if we are looking for square integrable solutions, we need to know the asymptotic behaviours of these functions for large values of z , which are,

$$I_{\ell+\frac{1}{2}}(z) \sim \frac{e^z}{\sqrt{2\pi z}}, \quad K_{\ell+\frac{1}{2}}(z) \sim \sqrt{\frac{\pi}{2z}} e^{-z}. \quad (3.11)$$

Accordingly, the solution (3.10) is square integrable if and only if $C_\ell = 0$. In this way, the only possible contribution comes from the second term, so that

$$u_\ell(r) = D_\ell \sqrt{\kappa r} K_{\ell+\frac{1}{2}}(\kappa r), \quad r \in (R, \infty) \quad \ell \in \mathbb{N}_0. \quad (3.12)$$

Once we have obtained the solutions inside and outside the nucleus, we need to link both of them at the point $r = R$ in an appropriate way.

3.3. Matching conditions at $r = R$

As established by the standard bibliography on the subject [11], there are requirements for the reduced radial function at the point $r = R$ which fix a self adjoint determination of the operator

$$-\frac{d^2}{dr^2} + \frac{\ell(\ell+1)}{r^2} + \frac{2\mu V_0}{\hbar^2} [\theta(r-R) - 1],$$

in such a way that the final Hamiltonian is just the one considered in (3.1). These requirements are given by matching conditions relating the function $u_\ell(r)$ and its first derivative at the limit values of R . They can be written in terms of a $SL(2, \mathbb{R})$ matrix as [12, 38, 39]

$$\begin{pmatrix} u_\ell(R^+) \\ u'_\ell(R^+) \end{pmatrix} = \begin{pmatrix} \frac{2+\beta}{2-\beta} & 0 \\ \frac{4\alpha}{4-\beta^2} & \frac{2-\beta}{2+\beta} \end{pmatrix} \begin{pmatrix} u_\ell(R^-) \\ u'_\ell(R^-) \end{pmatrix}, \quad u_\ell(R^\pm) = \lim_{x \rightarrow R^\pm} u_\ell(x). \quad (3.13)$$

The function $u_\ell(r)$ is given by (3.7) and (3.12). As already mentioned, there is a rigorous discussion on the self adjointness of the resulting Hamiltonian in Appendix A. The matrix relation (3.13), together with (3.7) and (3.12), yields the following secular equation:

$$\frac{\chi J_{\ell+\frac{3}{2}}(\chi)}{J_{\ell+\frac{1}{2}}(\chi)} = \frac{(2+\beta)^2 \sigma K_{\ell+\frac{3}{2}}(\sigma)}{(2-\beta)^2 K_{\ell+\frac{1}{2}}(\sigma)} - \frac{8\beta(\ell+1)}{(2-\beta)^2} + \frac{w_{\ell j}}{(2-\beta)^2}. \quad (3.14)$$

We will denote the left-hand side by $\varphi_\ell(\chi)$ and the right-hand side⁶ by $\phi_\ell(\sigma)$, so (3.14) is written as $\varphi_\ell(\chi) = \phi_\ell(\sigma)$. For simplicity, we have introduced the following auxiliary variables

$$\chi = v_0 \sqrt{1-\varepsilon}, \quad \sigma = v_0 \sqrt{\varepsilon}, \quad (3.15)$$

and defined the dimensionless parameters, v_0 , $w_{\ell j}$ and the *relative energy* ε as

$$v_0 = \sqrt{\frac{2\mu R^2 V_0}{\hbar^2}} > 0, \quad w_{\ell j} = \frac{-8\mu V_{so} \xi_{\ell j} R}{\hbar^2}, \quad \varepsilon = |E|/V_0 \in (0, 1). \quad (3.16)$$

The secular equation (3.14) does not admit closed-form solutions for the energy of bound states and it will be analyzed in the forthcoming section.

4. General properties of the spherical well plus the δ - δ' interaction

In the previous section we have established the matching conditions that radial wave functions must fulfil so that the δ and the local δ' interactions are well defined. With this, in the present section we consider all the terms in the Hamiltonian (3.1) in order to study the existence and properties of bound states. Moreover, we consider the cases for which the matching conditions are ill defined in section 4.1 and give a simplified secular equation for large-parameter configurations in section 4.2.

Before proceeding with our presentation, let us denote by $j_{\lambda,s}$ the s -th strictly positive zero of $J_\lambda(x)$, $\lambda > 0$. As is well known, these zeros satisfy

$$j_{\lambda,0} \equiv 0 < j_{\lambda,s} < j_{\lambda+1,s} < j_{\lambda,s+1}, \quad s \in \mathbb{N}. \quad (4.1)$$

We begin with a result concerning the existence and number of bound states, whose proof is given in Appendix B.1.

⁶ Observe that $\phi_\ell(\sigma)$ also depends explicitly on j and β .

Proposition 1 *If for any value $\ell \in \mathbb{N}_0$ such that $\ell \leq \ell_{\max}$ the following inequality holds*

$$w_{\ell j} > -((\beta - 2)^2 + 2\ell(\beta^2 + 4)), \quad (4.2)$$

there exists one, and only one, energy level with relative energy

$$\varepsilon_s \in \left(1 - \frac{j_{\ell+1/2,s}^2}{v_0^2}, 1 - \frac{j_{\ell+3/2,s-1}^2}{v_0^2}\right) \subset (0, 1), \quad s \in \mathbb{N}. \quad (4.3)$$

In addition, for $w_{\ell j} \in \mathbb{R}$ the final number of bound states, $N_\ell = (2\ell + 1)n_\ell$, is determined by

$$n_\ell = M + m - m', \quad (4.4)$$

where M is

$$M = \min\{s \in \mathbb{N}_0 \mid j_{\ell+1/2,s+1} > v_0\}, \quad (4.5)$$

and, using the functions $\varphi_\ell(\chi)$ and $\phi_\ell(\sigma)$ defined in (3.14),

$$m = \begin{cases} 1 & \text{if } \varphi_\ell(v_0) > \phi_\ell(0^+), \\ 0 & \text{if } \varphi_\ell(v_0) < \phi_\ell(0^+) \text{ or } v_0 = j_{\ell+1/2,M}, \end{cases} \quad m' = \begin{cases} 1 & \text{if } 0 > \phi_\ell(v_0), \\ 0 & \text{if } 0 < \phi_\ell(v_0). \end{cases} \quad (4.6)$$

Observe that the cases $\varphi_\ell(v_0) = \phi_\ell(0^+)$ and $\phi_\ell(v_0) = 0$ are a priori excluded from the present study. The same holds true for the possible bound states with energy below the potential well, which can arise if $\phi_\ell(v_0) < 0$. We have focused on the states which are relevant for the proposed nuclear model. In addition, it is interesting to point out that the structure of the energy intervals (4.3) is unaffected by the δ' interaction as long as (4.2) holds. Moreover, the number of bound states is mainly determined by M . For example, in figure 1 we observe that this number remains the same for different values of β . The same conclusion holds for the isotope ^{209}Pb , as will be shown in the next section. This fact could eventually justify the interpretation of this δ' interaction as an extra mean-field interaction less important than the spin-orbit term.

Figure 1. Bound states from the secular equation (3.14): the left-hand φ_ℓ side in blue, the right-hand side ϕ_ℓ in yellow for $\beta = -10$, green for $\beta = 0$, red for $\beta = 10$, and purple for $\beta = \pm\infty$. The figure on the left corresponds to $\ell = 0$, the figure on the right to $\ell = 4$. In both cases, the values of the relevant parameters are chosen to be $v_0 = 12$, $w_{\ell j} = 30$.

In proposition 1, we have assumed the existence of an upper bound for the angular momentum, ℓ_{\max} . For spherically symmetric potentials, satisfying $\int_0^\infty |V(r)| r^t dr < \infty$ for $t = 1, 2$, the inequality

$$n_\ell < \frac{1}{2\ell + 1} \int_0^\infty r |V_-(r)| dr, \quad V_-(r) = \min(\{V(r), 0\}), \quad (4.7)$$

ensures the existence of this upper bound [40]. For the δ potential alone, the existence of ℓ_{\max} is guaranteed. As a matter of fact, it can be shown that a particular linear combination of δ potentials saturates the previous inequality [41]. When we add the δ' term, the argument of Bargmann [40] for the existence of ℓ_{\max} does not apply any more, since it is then unclear how to interpret the previous integral. Fortunately, the following result, for which the proof is given in Appendix B.2, guarantees the existence of this bound in the present configuration. Furthermore, it also provides a simple expression for ℓ_{\max} .

Proposition 2 *There are no bound states with angular momentum $\ell > \ell_{\max}$, where*

$$\ell_{\max} = \max\{\ell \in \mathbb{N}_0 \mid j_{\ell+1/2,1} < v_0 \text{ or } \varphi_\ell(v_0) > \phi_\ell(0^+)\}.$$

If there exist $s_0 \in \mathbb{N}$ and $\ell_0 \in \mathbb{N}_0$ such that $v_0 = j_{\ell_0+1/2,s_0}$ the second condition in the previous set can not be evaluated. Nonetheless, it is not necessary since the existence of at least one bound state for ℓ_0 is guaranteed.

Concerning the ordering of bound states, we can prove an important result, that will be useful in the sequel. For spherically symmetric potentials, we know that if $E_{n\ell}$ denotes the energy of a bound state defined by the quantum numbers n and ℓ the following inequalities hold,

$$E_{n\ell} < E_{(n+1)\ell} < E_{(n+1)(\ell+1)}, \quad n, \ell \in \mathbb{N}_0. \quad (4.8)$$

This statement can be derived for continuous potentials using Sturm's theorem analysing the spectral properties of the Hamiltonian [42]. Now, we extend this result for the spherically symmetric δ - δ' interaction we are dealing with (3.1), where we have to take into account that another quantum number j appears. The proof of the following result is given in Appendix B.3.

Proposition 3 *If there exist bound states with relative energies $\varepsilon_{n\ell_j}, \varepsilon_{(n+1)\ell_j}, \varepsilon_{n(\ell+1)_j}$ for $n, \ell \in \mathbb{N}_0$ the following inequalities hold:*

$$(a) \quad -\varepsilon_{n\ell_j} < -\varepsilon_{(n+1)\ell_j}, \quad (b) \quad -\varepsilon_{n\ell_j} < -\varepsilon_{n(\ell+1)_j}, \quad (c) \quad -\varepsilon_{n\ell_{\ell+1/2}} < -\varepsilon_{n\ell_{\ell-1/2}}. \quad (4.9)$$

Notice that the second inequality only applies for $j = \ell + 1/2$ and the third inequality for $\ell > 0$. These results are in agreement with the experimental data. Inequalities (a) and (b) are well known in nuclear physics when dealing with spherically symmetric potentials [43, 44], as it was already mentioned in (4.8). With respect to inequality (c), it is worth mentioning that the microscopic quantum description of nucleons inside the nuclei, requires a careful treatment of the orbital angular momentum with the intrinsic nucleon spin. It was connected with the long standing problem in nuclear physics related to the inability to theoretically explain the magic numbers in atomic nuclei. Only when this interaction was included in the mean-field shell model, all experimental magic number were explained. In the course of this breakthrough it was found that, contrary to atomic electrons, the nucleon which is aligned with the orbital angular momentum is more strongly attracted, as it comes out from our model.

Lastly, a brief comment on the ground state. For a single particle Schrödinger equation it can be shown, using the variational principle, that the ground state must be a spherically symmetric zero angular momentum state [45]. For the spherical well considered this statement can be directly proved using the monotonicity properties of $\varphi_\ell(\chi(\varepsilon))$ and $\phi_\ell(\sigma(\varepsilon))$. Indeed, in this case $w_{\ell j} = 0$ and $\beta = 0$ so the right-hand of the secular equation (3.14) is strictly positive.

However, with the results shown, this could seem to be no longer true when we add the δ - δ' interaction. In fact, it would be enough to include the δ potential. For example, there exists configurations with bound states for $\ell = 1$ and not for $\ell = 0$. Although a two particle system with strong spin-orbit coupling can end up with a non-zero angular momentum ground state [46], in the above-mentioned configurations the $\ell = 0$ bound state exists. As we have already mentioned after proposition 1, an attractive δ coupling such that $\phi_\ell(v_0)$ involves a bound state with energy below $-V_0$, whereas we are focusing on states lying within $(-V_0, 0)$, see section 3.1. It is worth mentioning that the δ - δ' interaction without the spherical well also presents bound states with angular momentum $\ell \in \{0, 1, \dots, \ell_{\max}\}$. This statement has been proved in proposition 2 of [38].

4.1. Special cases $\beta = \pm 2$

Let us go back to the matching conditions (3.13). They do not apply for the exceptional values $\beta = \pm 2$. Nevertheless, there exist respective self adjoint extensions of the radial Hamiltonian for these cases [11]. They are characterized by the following boundary conditions at $r = R$:

$$\begin{aligned} u_\ell(R^+) - \frac{4}{\alpha} u'_\ell(R^+) &= 0, \quad u_\ell(R^-) = 0, & \text{if } \beta = 2, \\ u_\ell(R^-) + \frac{4}{\alpha} u'_\ell(R^-) &= 0, \quad u_\ell(R^+) = 0, & \text{if } \beta = -2. \end{aligned}$$

These situations have already been studied, for instance in [39], where it is shown that in both cases the contact interaction becomes an opaque barrier, which means that the transmission coefficient is equal to zero. This suggests that there are only bound states, in an infinite number, plus scattering states and no resonances whatsoever. We may give an estimation of the values and number of bound states when $\beta \rightarrow \pm 2$.

First of all, taking the limit $\beta \rightarrow 2$ in (3.14) when $\text{sgn}(\phi_\ell(0^+)\phi_\ell(v_0)) = 1$ we obtain $|\phi_\ell(\sigma)| \rightarrow \infty$. Therefore, the acceptable values of χ in the same equation are, essentially, the zeros of $J_{\ell+1/2}(\chi)$. Hence, from $\chi = v_0\sqrt{1-\varepsilon}$, we conclude that the i -th bound state with relative energy ε_i is given by

$$\lim_{\beta \rightarrow 2} \varepsilon_i = 1 - \left(\frac{j_{\ell+1/2,i}}{v_0} \right)^2. \quad (4.10)$$

Notice that the first energy value, ε_1 , is not reached if $\text{sgn}(\phi_\ell(0^+)) = -1$. Secondly, in the limit $\beta \rightarrow -2$ equation (3.14) reduces to

$$\frac{\chi J_{\ell+\frac{3}{2}}(\chi)}{J_{\ell+\frac{1}{2}}(\chi)} = \left(\ell + 1 + \frac{w_{\ell j}}{16} \right). \quad (4.11)$$

This transcendental equation is far simpler than (3.14) since the right-hand side is independent of v_0 and the relative energy.

4.2. Large-parameter configurations

The main aim of this section is to show that for certain values of the parameters $v_0, w_{\ell j}$ and β remarkable simplifications in the bound state structure occur. To begin with, let us consider $v_0 \gg 0$. Hence, using the limiting forms of the Bessel functions for large values of their arguments [47], the secular equation (3.14) can be approximated by

$$\chi \cot \left(\frac{\pi \ell}{2} - \chi \right) = \frac{(\beta + 2)^2 \sigma - 8\beta(\ell + 1) + w_{\ell j}}{(\beta - 2)^2}. \quad (4.12)$$

It is important to note that the previous equation only differs from the zero angular momentum secular equation by the term $8\beta(\ell + 1) = 8\beta$. Consequently, for the δ potential alone and $\ell = 0$, equation (3.14) takes the following simple form:

$$-\chi \cot \chi = \frac{w_{\ell j}}{4} + \sigma. \quad (4.13)$$

In this regard, we should mention that this approach is valid for low angular momentum values only. For instance, after (4.12) we can not conclude the existence of the maximal angular momentum ℓ_{\max} defined in proposition 2.

If, in addition, we consider $|w_{\ell j}| \gg |\beta|$ so that the right-hand side of (4.12) is nearly independent of ε , the energy of the bound states can be obtained, in an approximate form, from the zeros of $\sin \left(\frac{\pi \ell}{2} - v_0\sqrt{1-\varepsilon} \right)$, i.e.,

$$\varepsilon_n \simeq 1 - \left(\frac{\pi(\ell - 2n)}{2v_0} \right)^2 \in (0, 1), \quad n \in \mathbb{Z}. \quad (4.14)$$

Then, we may estimate the number of bound states for a given value ℓ of the angular momentum as

$$N_\ell = n_\ell(2\ell + 1) \quad \text{with} \quad n_\ell \simeq \left\lfloor \frac{\pi \ell + 2v_0}{2\pi} \right\rfloor \simeq \left\lfloor \frac{v_0}{\pi} \right\rfloor, \quad (4.15)$$

where the number of negative energy values n_ℓ has been obtained from (4.14), under the condition $\varepsilon_n > 0$.

Finally, irrespective of the previous considerations, we analyse a system characterized by a very strong δ' interaction, that is to say, we take the limit $|\beta| \rightarrow \infty$ in the secular equation (3.14). As can be easily checked, this situation is equivalent to the non-existence of the δ - δ' interaction, i.e., $\alpha = \beta = 0$. For this particular example, the matching conditions (3.13) impose the continuity of the radial function and its first derivative. The resulting secular equation matches with the one found for the finite three-dimensional spherical potential well, usually derived imposing the continuity of the logarithm derivative of the radial function at R [42].

5. Neutron energy levels of ^{133}Sn and ^{209}Pb

The purpose of this section is to apply the general results previously obtained to realistic physical situations. We begin comparing the energy levels for some states of the nucleus ^{133}Sn achieved using the square well plus the δ potential with the numerical values obtained using the Gamow code [26]. The energy values of the δ - δ' model (δ - δ' M) are obtained through (3.14), where the numerical values of the physical parameters are $V_0 = 39.5$ MeV, $V_{so} = 15.5$ MeV fm, $r_0 = 1.27$ fm, $2\mu/\hbar^2 = 0.0479$ MeV $^{-1}$ fm $^{-2}$, $R = 6.47$ fm and $V_q = 0$ [48], which determine the values of $v_0 = 8.89$, $w_{\ell j} = -19.20 \xi_{\ell j}$ see (3.16). Some results are shown in table 2, where we can see that the inequalities of (4.9) are always satisfied. For these low-lying bound states we obtain a quantitatively fair approximation. For this simulation we have taken $a = 0.05$ fm.

Table 2. Neutron energy levels (MeV) for $\ell = 0$ and $\ell = 1$ in the nucleus ^{133}Sn , using the physical parameters mentioned in the text.

State ($n\ell_j$)	Gamow	δ - δ' M
$0s_{1/2}$	-35.52	-35.53
$1s_{1/2}$	-23.81	-23.83
$2s_{1/2}$	-5.56	-5.59
$0p_{1/2}$	-31.37	-30.79
$1p_{1/2}$	-15.95	-14.20
$0p_{3/2}$	-31.42	-31.95
$1p_{3/2}$	-16.08	-17.46

Firstly, in table 3, we compare the numerical [26] and experimental energies, taken from the Database of the National Nuclear Data Center Brookhaven National Laboratory [48] and [49], for the isotope ^{209}Pb . The relevant parameters describing the lowest experimental energy states are $V_0 = 44.4$ MeV, $V_{so} = 16.5$ MeV fm, $r_0 = 1.27$ fm ($R = 7.525$ fm), and $2\mu/\hbar^2 = 0.0480$ MeV $^{-1}$ fm $^{-2}$ [48]. For the present configuration $v_0 = 10.98$, $w_{\ell j} = -23.83 \xi_{\ell j}$. With this comparison we ascertain that the program we are using to test our model fits with the available experimental data.

Table 3. Comparison of the numerical (Gamow code) energy levels (MeV) in ^{209}Pb with the experimental ones, using the physical parameters mentioned in the text.

State ($n\ell_j$)	Gamow	E_{exp}
$1g_{9/2}$	-3.93	-3.94
$2p_{1/2}$	-8.47	-6.73
$2p_{3/2}$	-9.17	-7.62
$0i_{11/2}$	-2.80	-3.16
$2d_{5/2}$	-2.07	-2.37
$0j_{15/2}$	-1.88	-2.51

Now we add the δ' interaction for this nucleus. In figure 2, we use the parameters given above for $\ell = 0$ and $\ell = 1$, where the energy of the bound states is given in table 4. We also compare these results with those obtained with the Gamow code [26]. We have chosen $\beta = 0$ and $\beta = 1$, which corresponds to $V_q = 0$ and $V_q = -20.83$ MeV fm 2 , respectively. The numerical approximation of the square well and singular potentials in table 4 are simulated taking $a = 0.01$ fm. From table 4, we observe that there are three bound states for both values $\beta = 0$ and $\beta = 1$. The same number of bound states is obtained when we consider the δ - δ' model, see figure 2.

In table 4 we have observed some discrepancies between the results obtained with our formalism and the numerical calculations obtained when considering the δ' interaction as a limit of odd functions. This is to be expected and origin lies in the different definitions of the δ' interaction explained at the end of section 2. Nevertheless, our intention is to show how these differences vary with the quantum numbers (n, ℓ, j). In the data of table 4 we can also verify that the inequalities of (4.9) are always satisfied when the δ' term is added.

Figure 2. Results for the isotope ^{209}Pb . In blue the left-hand side φ_ℓ of (3.14) in yellow the right-hand side ϕ_ℓ for $\beta = 1$. On the left the case $\ell = 0$, on the right the case $\ell = 1$ and $j = 3/2$.

Table 4. Comparison of the neutron energy levels (MeV) in the core of ^{208}Pb between the numerical Gamow code results [26] versus our model (δ - δ' M) results, using the physical parameters mentioned in the text. Calculations are done for $\beta = 0$ and $\beta = 1$.

State	$\beta = 0$		$\beta = 1$	
	Gamow	δ - δ' M	Gamow	δ - δ' M
$0s_{1/2}$	-41.35	-41.36	-40.97	-40.84
$1s_{1/2}$	-32.27	-32.31	-31.11	-30.23
$2s_{1/2}$	-17.53	-17.61	-18.11	-12.91
$0p_{1/2}$	-38.08	-37.80	-37.34	-37.10
$1p_{1/2}$	-25.91	-25.04	-24.44	-22.90
$2p_{1/2}$	-8.47	-6.67	-11.20	-2.38
$0p_{3/2}$	-38.21	-38.54	-37.48	-37.15
$1p_{3/2}$	-26.29	-27.18	-25.30	-23.16
$2p_{3/2}$	-9.17	-10.63	-13.30	-4.31

6. Resonances

Solvable or quasi-solvable models usually have, in addition to bound states, resonances (unstable or quasi-stable quantum states) and possibly anti-bound states. The study of resonance models is necessary because most of the known quantum states are unstable. For example, single-particle resonances appear in the dripline of light nuclei, such as ^5He , ^8B , and ^{10}Li . Resonance models give a qualitative account for resonance behaviour and, therefore, may give a good insight into the quantum properties of quantum unstable states. In this paper, we are assuming that resonances appear in resonance scattering, which is produced by a Hamiltonian pair $\{H_0, H = H_0 + V\}$. Thus, a resonance arises when the incoming particle stays in the region where the potential acts, a much longer time than the one it would have stayed if the potential had not existed.

There are several definitions of resonances based on either physical or mathematical notions, which are not always equivalent. Because of the kind of model presented here, we are using the concept of resonance as given in mathematical terms. There are essentially two approaches, either we define resonances as poles of analytic continuations of a “reduced” resolvent of the total Hamiltonian [50], or as poles of an analytic continuation of the S -matrix in the momentum representation (or equivalently in the energy representation). Here, we shall adopt the second point of view.

Under some general conditions based in causality principles [51], the S matrix in momentum representation, denoted as $S(k)$, admits an analytic continuation to a meromorphic function of the complex variable k on the whole complex plane. It is meromorphic because $S(k)$ has poles, which may be classified in three types:

- Simple poles on the positive half of the imaginary axis that correspond to bound states.
- Simple poles in the negative half of the imaginary axis, which represent the presence of the antibound (virtual) states.
- Pair of poles on the lower half plane, symmetrically located with respect to the imaginary axis, each of these pairs representing one resonance [51, 52].

Although the order of resonance poles may be in principle arbitrary (both poles of each pair must have the same multiplicity), in general they are simple. This result emerges from our particular model.

If we go from the momentum to the energy representation, $E = \hbar^2 k^2 / (2\mu)$, poles for each resonance pair become two conjugate complex numbers of the form $z_R = E_R - i\Gamma/2$ and $z_R^* = E_R + i\Gamma/2$, with $\Gamma > 0$. Here, E_R represents the resonance energy, usually $E_R > 0$, and Γ the inverse of the half life. After this comment, one may understand that in the momentum representation, the closer a resonance pole is to the real axis, the higher is its mean life.

Without further ado, let us study the resonances in the present case. In section 3.2, we have written the wave equation outside the nucleus as a linear combination of modified Bessel functions of first and second kind. The requirement of square integrability, needed to characterize bound states, forced us to drop the contribution of the Bessel function of first kind and just keep the Bessel function of second kind. Resonance state functions, also called Gamow functions, are not square integrable so we can simply solve Schrödinger equation outside the nucleus for $E > 0$. This leads to a solution analogous to (3.5) in terms of Bessel and Neumann functions. Nevertheless, for reasons that will be evident below, it is convenient to write this solution in terms of the H ankel functions as

$$u_\ell(r) = \sqrt{\kappa r} \left(C_\ell H_{\ell+\frac{1}{2}}^{(1)}(\kappa r) + D_\ell H_{\ell+\frac{1}{2}}^{(2)}(\kappa r) \right), \quad \kappa = \frac{\sqrt{2\mu E}}{\hbar}, \quad E > 0, \quad (6.1)$$

where C_ℓ and D_ℓ are independent of r , although they depend on κ . This expression is valid for $r > R$. The superscripts distinguish between the H ankel functions of first (1) and second kind (2). These functions present the following asymptotic behaviour [47] for large values of r :

$$H_{\ell+\frac{1}{2}}^{(1)}(\kappa r) \sim \sqrt{\frac{2}{\pi \kappa r}} e^{-i(\kappa r - (\ell+1)\pi/2)}, \quad \text{if } -\pi < \arg z < 2\pi, \quad (6.2)$$

$$H_{\ell+\frac{1}{2}}^{(2)}(\kappa r) \sim \sqrt{\frac{2}{\pi \kappa r}} e^{i(\kappa r - (\ell+1)\pi/2)}, \quad \text{if } -\pi < \arg z < 2\pi. \quad (6.3)$$

Consequently, $H_{\ell+1/2}^{(1)}(\kappa r)$ can be interpreted as an outgoing wave function, while $H_{\ell+1/2}^{(2)}(\kappa r)$ as an incoming wave function. Resonances are given by the so called *purely outgoing boundary condition*, which states that only the outgoing wave function survives. This is satisfied if and only if $D_\ell = 0$ in (6.1). At first look, this may resemble to the requirement $C_\ell = 0$ for (3.10), although the situation here has a completely different origin. Furthermore, the transcendental equation $D_\ell(\kappa) = 0$ gives us the poles of the S -matrix, which are the resonant poles.

In order to obtain these poles in the momentum representation and, after that, proceed with the construction of the resonance Gamow wave functions, we also use the matching condition (3.13) between the outgoing function and the wave function inside the potential well previously calculated in section 3.1. This gives the following transcendental equation in k

$$H_{\ell+\frac{1}{2}}^{(1)}(R\kappa) \left[8(\alpha R - \beta) J_{\ell+\frac{1}{2}}(R\gamma) - (\beta - 2)^2 R\gamma J_{\ell+\frac{3}{2}}(R\gamma) + (\beta - 2)^2 R\gamma J_{\ell-\frac{1}{2}}(R\gamma) \right] \\ + (\beta + 2)^2 \kappa R J_{\ell+\frac{1}{2}}(R\gamma) H_{\ell+\frac{3}{2}}^{(1)}(R\kappa) - (\beta + 2)^2 \kappa R J_{\ell+\frac{1}{2}}(R\gamma) H_{\ell-\frac{1}{2}}^{(1)}(R\kappa) = 0. \quad (6.4)$$

The solutions of (6.4) should be classified in three categories, as previously explained. If we set $\ell = 0$, the situation simplifies enormously. In fact, (6.4) becomes

$$\frac{\tan(\gamma R)}{\gamma R} = -\frac{i(\beta - 2)^2}{(\beta + 2)^2 \kappa R + 4i\alpha R}. \quad (6.5)$$

When we choose $\beta = 0$ (absence of the term in δ'), $V_0 = 0$ ($\gamma = \kappa$) and $\ell = 0$, we recover well known results [2, 15]. Since the resonant poles are complex solutions in the momentum representation, let us use the following notation:

$$k_1 + ik_2 =: R\kappa, \quad R\gamma = \sqrt{v_0^2 + (k_1 + ik_2)^2}, \quad (6.6)$$

so that (6.5) may be written as

$$F(k_1, k_2) := \frac{\tan \sqrt{v_0^2 + (k_1 + ik_2)^2}}{\sqrt{v_0^2 + (k_1 + ik_2)^2}} + \frac{i(\beta - 2)^2}{(\beta + 2)^2 (k_1 + ik_2) + iw_{\ell j}} = 0. \quad (6.7)$$

Denoting the real and imaginary parts of the complex number z by $\text{Re } z$ and $\text{Im } z$, respectively, a simple analysis on (6.7) shows that

$$\text{Re } F(-k_1, k_2) = \text{Re } F(k_1, k_2) \quad \text{and} \quad -\text{Im } F(-k_1, k_2) = \text{Im } F(k_1, k_2). \quad (6.8)$$

We observe that (6.8) implies that the curves in the plane (k_1, k_2) given by $\text{Re } F(k_1, k_2) = 0$ and $\text{Im } F(k_1, k_2) = 0$ are symmetric with respect to the imaginary axis $k_1 = 0$. The behaviour of the solutions of equation (6.7) is shown in figure 3. Except for the intersections of these two curves in the negative imaginary semi-axis, antibound states, the ones in the lower half plane give the resonance poles. Two intersections symmetrically placed with respect to the imaginary axis $k_1 = 0$ give the same resonance. We also observe the existence of a bound state in

Figure 3. In blue $\text{Re } F(k_1, k_2) = 0$ and in red $\text{Im } F(k_1, k_2) = 0$, from (6.4) for $\ell = 0$. Bound states and resonances correspond to intersection of red and blue curves. The relevant parameters are chosen to be $v_0 = 5$, $w_{\ell j} = 10$ and $\beta = 1$.

the positive imaginary axis $k_2 > 0$. These results are compatible with those obtained for bound states earlier in this paper; when we set $k_1 = 0$ and $k_2 > 0$ in (6.7) we recover the secular equation for $\ell = 0$, see (4.12) and the comment underneath.

It is noteworthy that there is an infinite number of resonances which lie on the lower half plane without the real axis $k_2 = 0$. In fact, for $k_2 = 0$, the imaginary part of (6.7) is given by

$$\frac{(\beta^2 - 4)^2 k_1}{(\beta + 2)^4 k_1^2 + w_{\ell j}^2} = 0, \quad (6.9)$$

which implies $k_1 = 0$, so that all intersections should coincide on the origin, which is obviously not the case. This is important, since as a consequence of reasonable *causality conditions*, see [51], resonance poles should lie on the lower half plane in the momentum representation.

Equation (6.4) for $\ell \neq 0$ does not admit the kind of simplification yielding to (6.5). Nevertheless, it is still possible to give an estimation of the location of the first few resonances in the k plane as well as some antibound states. Our results have been depicted in figure 4, where the cases $\ell = 1, 2, 3, 4$ have been considered. Resonance poles are located at the intersections of red and blue curves right below the real axis. Antibound states poles are located at the intersections of blue and red curves on the negative imaginary axis. The structure of the solutions is similar to the case $\ell = 0$.

7. Concluding remarks

We have studied a spherical well plus a linear combination of a Dirac delta and a local δ' interaction, both located at the same radius, the well edge. Due to spherical symmetry, the problem reduces to a one dimensional one, by means of the radial Schrödinger equation. This contact potential localized at the edge of the well has been defined by using appropriate matching conditions satisfied by the radial wave functions. This configuration can be used to approximately describe the extra neutron energy levels of a double magic nucleus with spin-orbit

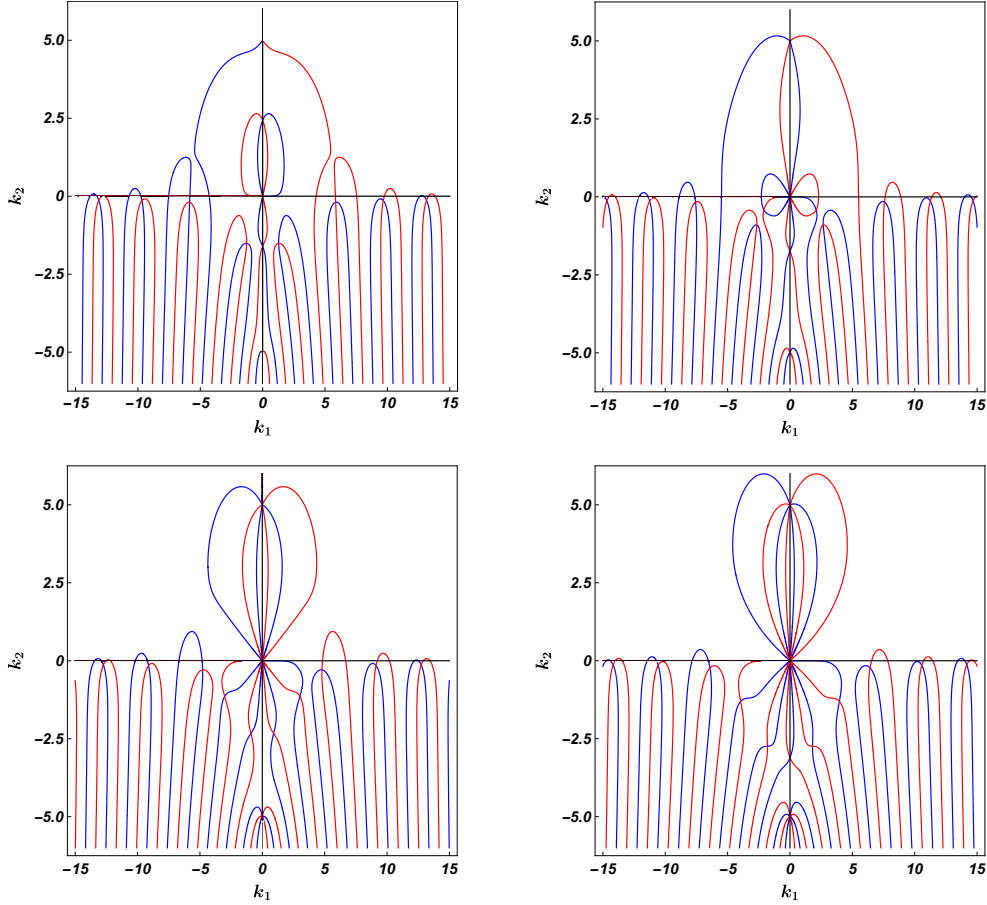

Figure 4. In blue the annihilation of the real part of (6.4) and in red the annihilation of the imaginary part. Bound states and resonances correspond to the intersection of red and blue curves. From top to bottom, and from left to right, the curves for $\ell = 1, 2, 3, 4$. In all the cases the relevant parameters are chosen to be $v_0 = 5$, $w_{\ell j} = 10$ and $\beta = 1$.

interaction plus an extra mean-field interaction, which may be related to the quadrupole interaction. We have performed a careful analysis of the properties of bound states. We have applied this model for the double magic configurations ^{209}Pb and ^{133}Sn .

We have shown that the Hamiltonian (2.13), resulting from the Woods-Saxon potential after the limit $a \rightarrow 0^+$, gives a good approximation for the values of the energy levels. This is quite accurate for low-lying bound states. The proposed model has the advantage over the Woods-Saxon model that all calculations are analytic and much simpler. In particular, we have obtained general and precise properties concerning the number and behaviour of bound states. These are summarized in the three propositions of section 4.

In the δ - δ' contact potential the δ term gives the approximation of the nuclear spin-orbit contribution. The aim of the additional interaction, given by the δ' interaction, is providing a correction such that the results of the proposed model better fit to the experimental data, in particular for states like the ones shown in table 3. As we have previously stated, this was the main motivation to employ the δ - δ' contact interaction: we can solve exactly the eigenfunction equation and obtain analytic properties of the spectrum taking advantage of well-known features of Bessel functions.

We have found that the dependence of bound states with the coefficient α of the δ potential is stronger than the dependence on the coefficient β of the δ' interaction. There are, nevertheless, some exceptions, the most interesting occurs when β reaches two critical points.

This model has also antibound states and resonances. These are characterized by the existence of poles in the analytic continuation, $S(k)$, of the S -matrix in the moment representation. These poles may also be obtained using the so-called *purely outgoing boundary conditions*, which are determined by equating to zero the

coefficient of the asymptotic form of the incoming wave. This coefficient depends on the momentum k , which gives a transcendental equation, for which the solutions are the poles of $S(k)$. Exact and numerical values for resonances, bound and antibound states can be obtained for all values of the orbital angular momentum, although the case $\ell = 0$ is by far the simplest.

Along our discussion, we have mentioned that there are two possible choices of the δ' interaction. We have chosen the only one which is compatible, in the sense that the resulting Hamiltonian be self adjoint, with the δ interaction supported at the same point, the so called local δ' interaction. We have obtained some numerical results, which slightly deviate from those obtained using the Gamow package. The reason is the way this package considers the limit $a \rightarrow 0^+$ in (2.12), leading to a δ' potential which does not give a self adjoint version of the Hamiltonian.

Finally, as mentioned in section 2, let us point out that although the Coulomb interaction has not been included in the present study, it can be introduced without an extraordinary effort. Work in this direction is presently in progress.

Appendix A. On the self adjointness of the Hamiltonian

The goal of the present appendix is a discussion on the self adjointness of the radial Hamiltonian (3.1). Setting the appropriate units such that $\hbar = 1$ and $2\mu = 1$ this Hamiltonian may be written as

$$H = -\frac{d^2}{dr^2} + [\theta(r - R) - 1]V_0 + a\delta(r - R) + b\delta'(r - R) + \frac{\ell(\ell + 1)}{r^2}, \quad \ell \in \mathbb{N}_0. \quad (\text{A.1})$$

Let us split it into $H = H_\ell + V(r)$, where

$$H_\ell = -\frac{d^2}{dr^2} + \frac{\ell(\ell + 1)}{r^2}. \quad (\text{A.2})$$

For the sake of clarity, we first study $H_{\ell=0}$, which reduces to the one-dimensional Laplace operator in a given domain.

Appendix A.1. Zero angular momentum

We have to find a domain for H_0 , which must be a subspace of $L^2[0, \infty)$. This domain must include all square integrable absolutely continuous functions, $f(r)$, with absolutely continuous derivative and square integrable second derivative. Thus,

$$\int_0^\infty \{|f(r)|^2 + |f''(r)|^2\} dr < \infty. \quad (\text{A.3})$$

The boundary conditions at the origin should be specified in such a way that H_0 is Hermitian on its domain. In consequence, for any $f(r), g(r)$ in the domain of H_0 ,

$$\begin{aligned} \langle h(r) | H_0 f(r) \rangle &= - \int_0^\infty h^*(r) f''(r) dr = h^*(0) f'(0) - h'^*(0) f(0) - \int_0^\infty h''^*(r) f(r) dr \\ &= h^*(0) f'(0) - h'^*(0) f(0) + \langle H_0 h(r) | f(r) \rangle. \end{aligned} \quad (\text{A.4})$$

Then, H_0 is Hermitian in the given domain if and only if $h^*(0) f'(0) - h'^*(0) f(0) = 0$, which happens if and only if $f(0) = c f'(0)$ for any function $f(r)$ in this domain, where c is an arbitrary real constant. For $c = 0$, we have that $f(0) = 0$ with $f'(0)$ arbitrary. Since $c^{-1} f(0) = f'(0)$, another possible choice is $f'(0) = 0$ with $f(0)$ arbitrary. Here, we may say that $c = \infty$. All these possible choices select a domain, \mathcal{D} , in which H_0 is self adjoint. We select any one of these.

After selecting a value of $c \in \mathbb{R} \cup \{\infty\}$, let us consider a subspace of \mathcal{D} , denoted by $\mathcal{D}(H_0)$. By definition, $f(r) \in \mathcal{D}(H_0)$ if and only if, $f(R) = f'(R) = 0$. Choosing $\mathcal{D}(H_0)$ as the domain of H_0 , we see that H_0 is symmetric (Hermitian), although not self adjoint, having deficiency indices $(2, 2)$.

In order to prove this latter statement, let us recall that the domain of the adjoint H_0^\dagger is determined by

$$\mathcal{D}(H_0^\dagger) = \{h(r) \in L^2[0, \infty) ; \exists g(r) \in L^2[0, \infty) ; \langle h(r) | H_0 f(r) \rangle = \langle g(r) | f(r) \rangle\}, \quad (\text{A.5})$$

for all $f(r)$ in $\mathcal{D}(H_0)$. To obtain a basis of the deficiency subspaces [53], we have to solve the equations $h''(r) = \pm i h(r)$, where the solutions must be in $\mathcal{D}(H_0^\dagger)$. Let us choose the sign plus first. We obtain two linearly independent solutions, which are:

$$h_1(r) = \begin{cases} C e^{-\frac{\sqrt{2}}{2} r} e^{-i\frac{\sqrt{2}}{2} r}, & \text{if } r > R, \\ 0, & \text{if } r < R, \end{cases} \quad (\text{A.6})$$

$$h_2(r) = \begin{cases} 0, & \text{if } r > R, \\ A e^{-\frac{\sqrt{2}}{2} r} e^{-i\frac{\sqrt{2}}{2} r} + \frac{A(1-c)}{1+c} e^{\frac{\sqrt{2}}{2} r} e^{i\frac{\sqrt{2}}{2} r}, & \text{if } r < R, \end{cases} \quad (\text{A.7})$$

where A and C are arbitrary constants. The linear independence of these two functions is obvious, so that they are a basis for the deficiency subspace corresponding to the plus sign. Similar analysis can be performed for the minus sign. This proves that the deficiency indices for H_0 with domain $\mathcal{D}(H_0)$ are precisely $(2, 2)$. In this circumstance, H_0 admits an infinite number of self adjoint extensions labelled by four independent real parameters. Domains for these self adjoint extensions are determined by matching conditions at the point $r = R$ as usual [11], where the exceptional cases $\beta = \pm 2$ are also included. The choice of the matching conditions (3.13) gives a two parametric family of self adjoint extensions, which proves the self adjointness of

$$H_r = -\frac{d^2}{dr^2} + a\delta(r - R) + b\delta'(r - R), \quad (\text{A.8})$$

which is (A.1) with $\ell = 0$ and without the term $V_0 [\theta(r - R) - 1]$. As we will explain at the end of the present appendix, adding this term to the potential does not change the self adjointness.

Appendix A.2. Higher angular momentum

For $\ell \geq 1$ we do not need to impose conditions at the origin of the type $f(0) = cf'(0)$, as the Hamiltonian (A.2) is essentially self adjoint when its domain is given by the Schwartz space supported on $\mathbb{R}^+ := [0, \infty)$. For these functions $f(0) = f'(0) = 0$, so that $h^*(0) f'(0) - h'^*(0) f(0)$ is automatically zero. Then, we define $\mathcal{D}(H_\ell)$, $\ell \neq 0$, to be the space of functions $f(r) \in L^2[0, \infty)$ satisfying the following conditions [37]:

- (i) $f(r)$ and $f'(r)$ are absolutely continuous.
- (ii) $-f''(r) + [\ell(\ell + 1)/r^2]f(r)$ is square integrable, i.e., it belongs to $L^2[0, \infty)$.
- (iii) $f(0) = 0$.
- (iv) $f(R) = f'(R) = 0$.

In order to obtain the deficiency subspaces for H_ℓ , we have to find the square integrable solutions of the following pair of differential equations:

$$h''(r) - \frac{\ell(\ell + 1)}{r^2} h(r) \mp i h(r) = 0. \quad (\text{A.9})$$

For the minus sign in (A.9), the general solution is given by [37] (p. 478):

$$u(r) = A r^{1/2} J_{\ell+1/2}(r\sqrt{i}) + B r^{1/2} Y_{\ell+1/2}(r\sqrt{i}), \quad (\text{A.10})$$

where $J_{\ell+1/2}$ and $Y_{\ell+1/2}$ are the Bessel and Neumann functions [54], respectively. Asymptotic properties of these functions show that [37, 54]:

$$r^{1/2} J_{\ell+1/2}(r\sqrt{i}) \notin L^2[1, \infty), r^{1/2} J_{\ell+1/2}(r\sqrt{i}) \in L^2[0, 1], \quad (\text{A.11})$$

$$r^{1/2} Y_{\ell+1/2}(r\sqrt{i}) \in L^2[1, \infty), r^{1/2} Y_{\ell+1/2}(r\sqrt{i}) \notin L^2[0, 1]. \quad (\text{A.12})$$

Therefore, the basis for the deficiency subspace with minus sign in (A.9) is given by the following pair of functions:

$$u_1(r) = \begin{cases} A r^{1/2} Y_{\ell+1/2}(r\sqrt{i}), & \text{if } r > R, \\ 0, & \text{if } r < R, \end{cases} \quad u_2(r) = \begin{cases} 0, & \text{if } r > R, \\ B r^{1/2} J_{\ell+1/2}(r\sqrt{i}), & \text{if } r < R, \end{cases} \quad (\text{A.13})$$

where A and B are constants. A similar result can be obtained for the plus sign in (A.9), so that the deficiency indices for H_ℓ with $\ell \neq 0$ are $(2, 2)$. Self adjoint extensions are obtained by suitable matching conditions at $r = R$ and depend on four real parameters. Again, the choice of matching conditions (3.13), where the exceptional cases $\beta = \pm 2$ are included, determines a self adjoint Hamiltonian of the form,

$$H_r := -\frac{d^2}{dr^2} + a\delta(r - R) + b\delta'(r - R) + \frac{\ell(\ell + 1)}{r^2}, \quad \ell \neq 0, \quad (\text{A.14})$$

which is (A.1) without the term $V_0 [\theta(r - R) - 1]$. Adding this term does not change anything in both cases ($\ell = 0$ and $\ell \neq 0$). Once we have determined the domains for which (A.8) and (A.14) are self adjoint, since the term $V_0 [\theta(r - R) - 1]$ is bounded and Hermitian, it is self adjoint. Now, the Kato-Rellich theorem [53] says that if H_r is self adjoint, so is $H_r + [\theta(r - R) - 1]V_0$. We conclude that it is possible to determine domains such that (A.1) is self adjoint for all values $\ell \in \mathbb{N}_0$.

Appendix B. Proofs of some results on the paper

In the present section we prove propositions 1, 2, and 3 posed in section 4. In order to simplify the notation we will denote $\varphi_\ell(\varepsilon) \equiv \varphi_\ell(\chi(\varepsilon))$ and $\phi_\ell(\varepsilon) \equiv \phi_\ell(\sigma(\varepsilon))$.

Appendix B.1. Proof of proposition 1

In the first place, we show that the right-hand side of (3.14) is positive and strictly growing as a function of the relative energy. As will be proved in proposition 2, there exists an upper bound for the angular momentum, ℓ_{\max} hence the term $8\beta(\ell + 1)$ is always finite. From Theorem 6 in [55] there exists the following bounds for the following ratio of modified Bessel functions:

$$\sqrt{\sigma^2 + \ell^2} + \ell + 1 \leq \frac{\sigma K_{\ell+3/2}(\sigma)}{K_{\ell+1/2}(\sigma)} < \sqrt{\sigma^2 + (\ell + 1)^2} + \ell + 1. \quad (\text{B.1})$$

Now we can use the first inequality of (B.1) together with (4.2) to derive:

$$\phi_\ell(\sigma) = \frac{(2 + \beta)^2}{(2 - \beta)^2} \frac{\sigma K_{\ell+3/2}(\sigma)}{K_{\ell+1/2}(\sigma)} - \frac{8\beta(\ell + 1)}{(2 - \beta)^2} + \frac{w_{\ell j}}{(2 - \beta)^2} > \frac{(\beta - 2)^2 + 2\ell(\beta^2 + 4) + w_{\ell j}}{(\beta - 2)^2} > 0.$$

In addition, using the Turan-type inequalities given in [56], we can prove the following relation:

$$\frac{d\phi_\ell(\sigma)}{d\sigma} = \frac{\sigma K_{\ell-1/2}(\sigma) K_{\ell+3/2}(\sigma) - \sigma K_{\ell+1/2}^2(\sigma)}{K_{\ell+1/2}^2(\sigma)} > 0. \quad (\text{B.2})$$

This shows that $\phi_\ell(\sigma)$ is a strictly growing positive function on the variable σ and, due to the definition of $\sigma(\varepsilon)$ (3.15), on ε .

On the other hand, if we show that $\varphi_\ell(\chi)$, the left-hand side of (3.14), is one to one and onto as a function between the following intervals:

$$\varphi_\ell(\chi) : (j_{\ell+3/2,s-1}, j_{\ell+1/2,s}) \subset (0, v_0) \mapsto (0, \infty), \quad s \in \mathbb{N}, \quad (\text{B.3})$$

we guarantee the unique existence of the bound state ε_s in (4.3). Thus, it will be enough to demonstrate that $\varphi_\ell(\chi)$ is strictly monotonic on χ and it covers the whole $(0, \infty)$ as $\chi \in (j_{\ell+3/2,s-1}, j_{\ell+1/2,s})$. In fact, the first derivative of $\varphi_\ell(\chi)$ meets

$$\frac{d\varphi_\ell(\chi)}{d\chi} = \chi \frac{J_{\ell+1/2}^2(\chi) - J_{\ell-1/2}(\chi) J_{\ell+3/2}(\chi)}{J_{\ell+1/2}^2(\chi)} > 0, \quad (\text{B.4})$$

where the equality follows from standard properties of the Bessel functions [47] and the second relation from the Turan-type inequalities [38, 56]:

$$J_n^2(\chi) - J_{n-1}(\chi) J_{n+1}(\chi) > \frac{J_n^2(\chi)}{n+1} > 0, \quad (\text{B.5})$$

where χ is real and $n > 0$, with $n = \ell + 1/2$. Finally, in the given intervals, the function $\varphi_\ell(\chi)$ is positive and

$$\lim_{\chi \rightarrow j_{\ell+3/2, s-1}} \varphi_\ell(\chi) = \varphi_\ell(j_{\ell+3/2, s-1}) = 0, \quad \lim_{\chi \rightarrow j_{\ell+1/2, s}^-} \varphi_\ell(\chi) = \infty. \quad (\text{B.6})$$

Now we focus on the second part of the proposition concerning the number of bound states (4.4). The key feature is the existence of an integer s_0 for which $(j_{\ell+3/2, s-1}, j_{\ell+1/2, s}) \cap (0, v_0) = \emptyset \forall s \geq s_0$. Let us examine this in greater detail. The largest integer M for which $(j_{\ell+3/2, M-1}, j_{\ell+1/2, M}) \subset (0, v_0)$ still holds is obviously given by

$$j_{\ell+1/2, M} < v_0, \quad j_{\ell+1/2, M+1} > v_0. \quad (\text{B.7})$$

Since $\varphi_\ell(\chi(\varepsilon))$ is strictly decreasing and $\phi_\ell(\sigma(\varepsilon))$ strictly increasing as functions of ε , the condition

$$\lim_{\varepsilon \rightarrow 0^+} \varphi_\ell(\chi(\varepsilon)) = \varphi_\ell(v_0) = v_0 J_{\ell+3/2}(v_0) / J_{\ell+1/2}(v_0) > \frac{(\beta-2)^2 + 2\ell(\beta^2+4) + w_{\ell j}}{(\beta-2)^2} = \lim_{\varepsilon \rightarrow 0^+} \phi_\ell(\sigma(\varepsilon)). \quad (\text{B.8})$$

implies the existence of an additional bound state whose energy is the closest to $\varepsilon = 0$. In the particular case $v_0 = j_{\ell+1/2, M}$ no additional bound state should be added to M . Independently, if

$$\lim_{\varepsilon \rightarrow 1^-} \varphi_\ell(\chi(\varepsilon)) = 0 > \lim_{\varepsilon \rightarrow 1^-} \phi_\ell(\sigma(\varepsilon)) \quad (\text{B.9})$$

no bound state satisfying $\varepsilon \in (1 - j_{\ell+1/2, 1}^2/v_0^2, 1)$ appears. Only if $j_{\ell+1/2, 1} > v_0$ the functions m and m' defined in the present proposition are not independent. Nevertheless, a bound state with relative energy $\varepsilon \in (0, 1)$ appears if, and only if, $\varphi_\ell(v_0) > \lim_{\varepsilon \rightarrow 0^+} \phi_\ell(\sigma)$ and $0 < \lim_{\varepsilon \rightarrow 1^-} \phi_\ell(\sigma)$ so that n_ℓ is also given by (4.4) and the proof is concluded.

Appendix B.2. Proof of proposition 2

For this proof we use the number of bound states given in equation (4.4) of proposition 1 in order to obtain

$$n_\ell = 0 \quad \forall \ell > \ell_{\max}. \quad (\text{B.10})$$

Note that in the derivation of (4.4), we have not used the assumption of the existence of ℓ_{\max} that appears at the beginning of Appendix B.1 so there is no circular reasoning. Due to the properties of the zeros of the Bessel function (4.1) and their asymptotic expressions for large order [47], there exists an integer ℓ_0 such that

$$j_{\ell+1/2, 1} > v_0, \quad \ell \geq \ell_0, \quad (\text{B.11})$$

and therefore $M = 0$. Eventually, we shall reach a value $\ell_{\max} \geq \ell_0$ such that

$$\lim_{\varepsilon \rightarrow 0^+} \varphi_\ell(\chi(\varepsilon)) = \varphi_\ell(v_0) = v_0 J_{\ell+3/2}(v_0) / J_{\ell+1/2}(v_0) < \frac{(\beta-2)^2 + 2\ell(\beta^2+4) + w_{\ell j}}{(\beta-2)^2} = \lim_{\varepsilon \rightarrow 0^+} \phi_\ell(\sigma(\varepsilon)), \quad (\text{B.12})$$

for all $\ell > \ell_{\max}$, hence $m = m' = 0$. In effect, the existence of ℓ_{\max} is a consequence of the dependence on the angular momentum of both sides in the previous inequality. It is clear that the right-hand side is a strictly increasing function with respect to ℓ . In addition, using Theorem 3 of [57] it can be easily proved that the left-hand side fulfils

$$\frac{\partial \varphi_\ell(v_0)}{\partial \ell} \leq 0. \quad (\text{B.13})$$

In consequence, if none of the conditions $j_{\ell+1/2, 1} < v_0$, $\varphi_\ell(v_0) > \phi_\ell(0^+)$ hold, there is no bound state.

In order to complete the proof, we should consider a configuration in which an integer $s_0 \in \mathbb{N}$ such that $v_0 = j_{\ell+1/2, s_0}$ exists. In such a case the condition $\varphi_\ell(v_0) > \phi_\ell(0^+)$ is ill defined. Nevertheless, if $s_0 > 1$ we know the existence of at least one bound state. Thus, we have to consider the next value of the angular momentum for which $v_0 \neq j_{\ell+1/2, s_0}$. If $s_0 = 1$ the bound state always exists, although, if $\phi_\ell(v_0) < 0$, its energy can be below $-V_0$. Thus, we have to consider the next value of the angular momentum for which $v_0 \neq j_{\ell+1/2, 1}$.

Appendix B.3. Proof of proposition 3

Throughout the proof we bear in mind the monotonicity properties of $\varphi_\ell(\varepsilon)$ and $\phi_\ell(\varepsilon)$ with respect to ε demonstrated in Appendix B.1.

- (a) The inequality (a) in (4.9) is just a consequence of $j_{\lambda,i} < j_{\lambda,i+1}$ given in (4.1).
- (b) To prove the inequality (b) in (4.9) we first take into account that the bound states characterized by n are determined, for a given ℓ , by the function $\varphi_\ell(\varepsilon)$ restricted to the interval $(a_{n\ell}, b_{n\ell})$, where

$$a_{n\ell} = 1 - \frac{j_{\ell+1/2,n+1}^2}{v_0^2}, \quad b_{n\ell} = 1 - \frac{j_{\ell+1/2,n}^2}{v_0^2}, \quad n \in \mathbb{N}_0.$$

We need to consider both functions $\varphi_\ell(\varepsilon)$, $\varphi_{\ell+1}(\varepsilon)$, and therefore both intervals $(a_{n\ell}, b_{n\ell})$, $(a_{n(\ell+1)}, b_{n(\ell+1)})$. Due to the properties of the zeros $j_{\ell+1/2,n}$ given in (4.1), the following relations are fulfilled:

$$a_{n(\ell+1)} < a_{n\ell}, \quad b_{n(\ell+1)} < b_{n\ell}.$$

Therefore, either (i) $b_{n(\ell+1)} \leq a_{n\ell}$, or (ii) $a_{n\ell} < b_{n(\ell+1)}$.

- If (i) is true, $(a_{n(\ell+1)}, b_{n(\ell+1)}) \cap (a_{n\ell}, b_{n\ell}) = \emptyset$ so $-\varepsilon_{n\ell_j} < -\varepsilon_{n(\ell+1)_j}$ holds trivially.
- If (ii) is true, then we have three disjoint intervals: $(a_{n(\ell+1)}, a_{n\ell})$, $(a_{n\ell}, b_{n(\ell+1)})$ and $(b_{n(\ell+1)}, b_{n\ell})$. If $\varepsilon_{n\ell_j} \in (b_{n(\ell+1)}, b_{n\ell})$ or $\varepsilon_{n(\ell+1)_j} \in (a_{n(\ell+1)}, a_{n\ell})$, then it is obvious that $-\varepsilon_{n\ell_j} < -\varepsilon_{n(\ell+1)_j}$. However, if $\varepsilon_{n\ell_j}, \varepsilon_{n(\ell+1)_j} \in (a_{n\ell}, b_{n(\ell+1)})$, the situation needs to be studied in detail. Let us prove first:

$$\varphi_\ell(\varepsilon_0) \geq \varphi_{\ell+1}(\varepsilon_0), \quad \phi_\ell(\varepsilon_0) < \phi_{\ell+1}(\varepsilon_0), \quad \varepsilon_0 \in (a_{n\ell}, b_{n(\ell+1)}). \quad (\text{B.14})$$

The first part results from (B.13), since it holds for $v_0 \in \mathbb{R}$, excluding the singularities of φ_ℓ [57]. For the second case, the bounds in (B.1) ensure

$$\frac{\sigma K_{(\ell+1)+3/2}(\sigma)}{K_{(\ell+1)+1/2}(\sigma)} - \frac{\sigma K_{\ell+3/2}(\sigma)}{K_{\ell+1/2}(\sigma)} > \sqrt{\sigma^2 + (\ell+1)^2} + \ell + 2 - \sqrt{\sigma^2 + (\ell+1)^2} + \ell + 1 = 1. \quad (\text{B.15})$$

Consequently, using (3.14), we reach

$$\phi_{\ell+1}(\varepsilon_0) - \phi_\ell(\varepsilon_0) > 1 + \frac{w_{(\ell+1)j} - w_{\ell j}}{(2 - \beta)^2}. \quad (\text{B.16})$$

In addition, for $\ell + 1$, $j = (\ell + 1) - 1/2$ so, bearing in mind (2.7), the parameter $w_{(\ell+1)j} > 0$. In a similar way, for ℓ , $j = \ell + 1/2$ and $w_{\ell j} < 0$. Consequently, the second inequality in (B.14) is proved. Now, we may prove $\varepsilon_{n(\ell+1)_j} < \varepsilon_{n\ell_j}$ by contradiction. Let us assume $\varepsilon_{n(\ell+1)_j} \geq \varepsilon_{n\ell_j}$. With (B.14) and the monotonicity with respect to ε above-mentioned, we find

$$\phi_\ell(\varepsilon_{n\ell_j}) \leq \phi_\ell(\varepsilon_{n(\ell+1)_j}) < \phi_{\ell+1}(\varepsilon_{n(\ell+1)_j}) = \varphi_{\ell+1}(\varepsilon_{n(\ell+1)_j}) \leq \varphi_{\ell+1}(\varepsilon_{n\ell_j}) \leq \varphi_\ell(\varepsilon_{n\ell_j}). \quad (\text{B.17})$$

From here it follows $\varphi_\ell(\varepsilon_{n\ell_j}) \neq \phi_\ell(\varepsilon_{n\ell_j})$, which is clearly absurd because $\varepsilon_{n\ell_j}$ is a bound state, and the equality, (3.14), must be satisfied.

- (c) The inequality (c) in (4.9) is proved taking into account that the only dependence on j in the secular equation (3.14) is through $w_{\ell j}$. As we have already pointed out, $w_{\ell(\ell-1/2)} > 0 > w_{\ell(\ell+1/2)}$. In consequence, ϕ_ℓ is greater for $j = \ell - 1/2$. Since φ_ℓ is independent of j we only need to consider the interval $(a_{n\ell}, b_{n\ell})$, for which the inequality is proved, as has been done before, by contradiction.
